Oxide scale behaviour on aluminium and steel under hot

Oxide scale forming on steel surfaces during hot rolling significantly affects the surface quality of the products. In view of this, scale deformation during hot rolling has been examined using laboratory rolling mills of a 1/4 scale, and the following findings have been obtained.

Oxide Scale Behavior in High Temperature Metal Processing

4, KCl and NaCl lower the melting point of the metal and damage the protective oxide layer causing corrosion (5). In hot corrosion, metals and alloys degrade at higher rates than in air oxidation with a porous, non-protective oxide scale formed at their surface and sulfides in the substrate. Superalloys are developed for

oxide scale by optical or scanning electron microscopy (using etchants containing 0.5-1% hydrochloric acid solutions in ethanol) [j, k, l]. The microstructure of the oxide scale is however not straightforward. For example, as shown in Fig. 3, wã¼stite appears dark relative to the magnetite, and haematite is the lightest of the etched oxide layers.

the blistered scale; this is confirmed also through cross-section observation. This result indicates that blisters form and grow in the following manner: when a blister initially forms, scale is delaminated at the scale/metal interface, then the steel is oxidized at the de-tatched-off surface, and, while scale continues to detach off the
